

Review of Version 1: Gabrielle Winterboer

Goal of project: An interactive map that showcases upcoming events in Kansas City, allowing users to filter based on date, time and neighborhood in KC. Secondary goal was to be able to apply logic to filter based on event type, ie concert or sports.

What has been done so far: So far, an interactive map pulls from Ticketmaster and Eventbrite, and can be filtered by date (Vignette 1). I lost time trying to get the map to filter based on location as well, so someone could change the city and not be localized to Kansas City. I thought it was a good idea I could implement, but based on how the ticketmaster API pulls events, I can not get it to work so I am going back to having just Kansas City events in order to deliver a working product.

Video of how it currently works:

[Video of project current state](#)

Issues: See video for description of issues

Issues I haven't solved: I am going to work to create event type filtering as first priority for Version 2, then when I solve that figure out how to filter the map based on KC Neighborhood (ie. Independence, West Bottoms, Power and Light, etc).

Help needed:

Milestones:

July 6: Reformat code to pull for Kansas City events only, add filtering for event type (categories of Music, Sports, Comedy, Theater, and Other).

July 13: Attempt to narrow down event location based on KC neighborhood, or by creating Map overlay that highlights neighborhoods.

July 20: Improve UX for visual setup of map, and events, populate links, that that when you click on the map, you can go to the site to purchase tickets.

July 27: Overflow, make UX and filtering adjustments to guarantee site runs smoothly, adjust map to be better centered on Kansas City.

Self-reflection:

I feel a little behind personally, I wish I had not spent so much time when I got stuck on the location filtering, and instead paused and moved onto another step, but that's okay, because I feel like I am still on track to finish! I was getting nervous, but breaking it down into milestones, I feel confident I can create a polished, finished project. It was a lot easier to implement the map than I thought it would be, based on leaflet. The hardest part for me was setting up the filters, because I would get one to work, then have to adjust it when I added another. I hadn't expected the ticketmaster and eventbrite APIs to pull events differently, so normalizing them to be similar for the map was something I hadn't necessarily accounted for, not that it was hard, I just didn't

realize I would have to do that. I am a graphic designer and don't do any coding outside of HTML, so this has taught me a lot about structuring longer code blocks, and the importance of the ordering of things, as in, for example, HTML CSS, order doesn't have as much emphasis. I don't like how my interface *looks* right now, so I may personally take a little time to clean it up and make it look more polished, even if it functions well, I want it to look clean and streamlined. I will save that for the end, though, as I know that's not the important part of this project. Overall, I have learned a lot! I am glad that I learned how to do this, and I realized I could probably, once I learn a little more, apply a similar python map application on my workplace's website! We have a community events page full of all our biometric community events across North Kansas city, and I could make a similar map widget that could be embedded in our website that shows people the location of local hospital events like screenings, fitness classes and blood drives.
